What makes us confident about the existence of quarks?

Fun facts:

- Neither quarks nor gluons ever observed as free particles (confinement)
- Only hadrons can be detected (bound states of quarks and gluons)
 - Mesons: $\bar{q}q$ -states $(\pi^{\pm 0}, K^{\pm}, \dots)$
 - Baryons: qqq-states (p, n, ...)
 - Anti-Baryons: q̄q̄q̄-states (p̄, ...)
- $\bullet\,$ Typical hadron size: $\sim 1~\text{fm}$

Wrap it up!

- Scattering experiments are our "magnifying-glass"
- Ab initio QCD calculation agree with experimental observations (will show you examples)

イロト イヨト イヨト イヨト

Scattering experiments

Elastic $e^- p \rightarrow e^- p$ scattering (Considered as Coulomb scattering)

- both point-like particles
- no recoil of proton $(\vec{p}'=0)$

Rutherford Scattering

(point-like, spin-less particles, non-relativistic)

$$\frac{d\sigma}{d\Omega}_{\textit{Rutherford}} = \frac{\alpha^2}{4E^2 \sin^4 \theta/2}$$

Mott-Scattering

 $(e^-$ with spin and relativistic)

$$\frac{d\sigma}{d\Omega}_{\rm Mott} \simeq \frac{\alpha^2}{4E^2\sin^4\theta/2}\cos^2\frac{\theta}{2}$$

Dirac-Scattering (both have spin-1/2)

イロト イポト イヨト イヨト

Scattering experiments

Elastic $e^- p \rightarrow e^- p$ scattering

 Proton: extended object at rest (charge distributed, no recoil)

$$\frac{d\sigma}{d\Omega} = \frac{d\sigma}{d\Omega}_{Mott} |F(\vec{q}^{\,2})|^2$$

• $F(\vec{q}^2)$ form factor is Fourier transform of charge distribution

$$F(\vec{q}^2) = \int \rho(\vec{r}) e^{i\vec{q}\vec{r}} d^3r$$

• At low \vec{q}^2 , deviations from 1 measure for proton charge radius

$$F(\vec{q}^2) \xrightarrow{\vec{q}^2 \simeq 0} 1 - rac{1}{6} \vec{q}^2 \vec{r}^2 + \dots$$

イロト イポト イヨト イヨ

• Experiment by Hofstadter 1954: First evidence proton has a finite size (\sim 0.74 fm)

Hofstadter (Nobel lecture 1961)

Scattering experiments

Elastic $e^- p \rightarrow e^- p$ scattering $\frac{d\sigma}{d\Omega} = \frac{\alpha^2}{4E^2 \sin^4 \theta/2} \frac{E'}{E} \left(\frac{G_E^2 + \tau G_M^2}{1 + \tau} \cos^2 \frac{\theta}{2} + 2\tau G_M^2 \sin^2 \frac{\theta}{2} \right) \qquad \tau = -\frac{q^2}{2M_P^2}$

- Electron ($m_e = 0$) point-like, proton extended recoiling object, both have spin
- Two elastic form factors (functions of q^2)

$$G_{E}(q^{2}) \xrightarrow{\tau \ll 1} \int e^{i\vec{q}\vec{r}}\rho(\vec{r})d^{3}r \stackrel{(q^{2}=0)}{=} 1$$
$$G_{M}(q^{2}) \xrightarrow{\tau \ll 1} \int e^{i\vec{q}\vec{r}}\mu(\vec{r})d^{3}r \stackrel{(q^{2}=0)}{=} 2.79$$

4-momentum transfer

$$q^{2} = (k - k')^{2} \stackrel{(m_{e}=0)}{\simeq} -4EE' \sin^{2}\frac{\theta}{2}$$

- Anomalous magnetic moment of proton another evidence for not being point-like
- But: does not prove substructure

(日) (周) (王) (王)

High-energy scattering experiments

Inelastic scattering

- Collision become inelastic when $E_{e^-} > 1 \text{ GeV}$ (SLAC, 1968: $E_{e^-} = 5 - 20 \text{ GeV}$)
- Invariant mass: $p_4^2 = (p_2 + q)^2$ (virtual photon: $Q^2 = -q^2 > 0$)
- Two degrees of freedom, e.g.,

$$x = -q^2/(2p_2 \cdot q), \qquad y = q \cdot p_2/p_1 \cdot p_2$$

Deep inelastic scattering ($Q^2 \gg m_p^2 y^2$)

$$\frac{d^2\sigma}{dxdQ^2} \simeq \frac{4\pi\alpha^2}{Q^4} \left[(1-y) \frac{F_2(x,Q^2)}{x} + y^2 F_1(x,Q^2) \right]$$

Observation

$F_i(x, Q^2) \rightarrow F_i(x)$ Bjorken scaling $F_2(x) = 2F_1(x)$ Callan-Cross relation

Photon scatters elastically from spin-1/2 constituent particles (partons) within proton

 e^{-} p_1 θ p_2 p_4 p_4 p_4

イロト イポト イヨト イヨト

Quark Modell — Eightfold Way of Gell-Mann (1962)

- Many hadrons are known (quantum number, masses)
- Fit to representations of SU_F(3) groups

 $3\otimes \bar{\mathbf{3}} \;(\mathrm{mesons}) \quad \mathbf{3}\otimes \mathbf{3}\otimes \mathbf{3} \;(\mathrm{baryons})$

• If so, particles (quarks) forming fundamental representation must exists.

Spin-0 mesons (nonet)

 $\Sigma^{-1} \frac{du}{d} \frac{1}{\sqrt{2}} \frac{u}{\sqrt{2}} \frac{u}$

Spin-1/2 baryons (octet)

Spin-3/2 baryons (decuplet)

イロト イポト イヨト イヨ

Today understood as flavor symmetry

Scattering experiments: Summary

 $e^-p \rightarrow e^-p$ scattering: nature of interaction of the virtual γ with proton depends on wavelength (or Q^2)

- Scattering at very low e[−] energies (λ ≫ r_P) equivalent to scattering with point-like spin-less particle
- At low e^- energies ($\lambda \sim r_P$) scattering equivalent to that from extended charged object
- At high e⁻ energies the wavelength
 (λ < r_P) Scattering from constituent quarks
 (partons). Used to resolve sub-structure of
 proton.

イロト 不得下 イヨト イヨト

Partonic picture of proton result of SLAC deep inelastic scattering.

Scattering experiments: Fast-forward many years

At very high energies ($\lambda \ll r_P$): Proton looks like sea of quarks & gluons.

$$\frac{d^2\sigma}{dxdQ^2} \simeq \frac{4\pi\alpha^2}{2xQ^4} [1+(1-y)^2] F_2(x,Q^2)$$

- F₂ not a delta-function (not all quarks have x = 1/3)
- Can calculate Q²-dependence caused by dynamics of quarks and gluons

QCD: quarks have color charge and interact via colored gluons as described by QCD (theory of the strong interaction)

(日) (同) (日) (日)

Parton distribution function

Probability distribution of quarks and gluons in (fast moving) proton with momentum fraction \boldsymbol{x}

- Parton model: all quarks have $x = 1/3 \rightarrow F_2$ = delta-function
- Extract f(x) from measurements of proton / neutron structure function
- Cannot predicted them from the theory (nonperturbative), only approximate
- deviations of parton distribution with Q^2 well described by QCD

イロト イヨト イヨト イヨト

Standard model of elementary particle physics

(Credits: Wikimedia Commons)

(CERN Mug)

Building blocks:

 Quantum Chromodynamic (QCD) (strong interaction of quarks and gluons)

イロト 不得下 イヨト イヨト

- Electroweak interaction (electromagnetic + weak interaction)
- Higgs sector
 (gives mass to ℓ, q, Z and W[±])

Quantum Chromodynamic (QCD)

Lagrange density describes dynamics of quarks and gluons (Euclidean)

$$\mathcal{L}_{ ext{QCD}} = rac{1}{4} F^{a}_{\mu
u}[A] F^{\mu
u,a}[A] - ar{\psi} \left(\gamma_{\mu} D_{\mu}[A] - m
ight) \psi$$

- Field strength tensor: $F^{a}_{\mu\nu} = \partial_{\mu}A^{a}_{\nu} \partial_{\nu}A^{a}_{\mu} g_{s}f^{abc}A^{b}_{\mu}A^{c}_{\nu}$
- Gluons: A^a_μ (massless gauge bosons, color-charge ightarrow self-int)
- Fermions: $\psi_a^f, \overline{\psi}_a^f$ (quark and anti-quark) (Flavour: f = u, d, s, c, b, t, Color: a = r, g, b)
- invariant under gauge transformations

Parameters

(scale & ren-scheme dependent, fixed through experiment)

- Strong coupling constant: gs
- Quark masses: $m = diag(m_u, m_d, m_s, ...)$

Action (Euclidean)

$$S_{\rm QCD} = \int d^4 x {\cal L}_{\rm QCD}$$

イロト 不得下 イヨト イヨト 二日

Path integral formalism Quantization of a generic field theory

Partition function of a Euclidean QFT as a path integral (formally)

$$Z=\int D\Phi\,e^{-S(\Phi)}$$

- Φ denotes all fields of the theory, $S(\Phi)$ is the action
- "formally" because integral may not be defined a priori
- DΦ integration over all paths

$$ightarrow$$
 on a finite lattice with N sites: $\int D\Phi \equiv \int \cdots \int \prod_{i=1}^N d\Phi_i$

Expectation value of an observable

$$\langle \mathcal{O} \rangle = \int D\Phi \, \mathcal{O}[\Phi] \, e^{-S(\Phi)}$$

イロン イロン イヨン イヨン

Path integral formalism Sketch for QCD

Partition function (formally)

$$Z = \int DA_{\mu} \int D\psi D\overline{\psi} \, e^{-(S_G + S_F)}$$

• $S_G \ldots$ Euclidean gauge action

$$S_G[A] = \frac{1}{4} \int d^4 x \, F^a_{\mu\nu}[A] F^a_{\mu\nu}[A],$$

• $S_F \dots$ fermion action: $\psi^{(f)}$ where $f = \{u, d, s, \dots\}$

$$S_F = \int dx^4 \, \overline{\psi} \, \underbrace{(\gamma_\mu D_\mu + m_0)}_{\text{"fermion matrix" } M} \psi \qquad ext{where} \quad D_\mu = \partial_\mu + i g_0 A_\mu$$

- "formally" because integral over DA not defined a prioi (gauge invariance)
 - \blacktriangleright have to fix a gauge (perturbation theory) \rightarrow additional terms to action
 - physical observables independent of gauge
 - often covariant gauges (unique in the context of perturbation theory)

$$S_{gfix} = \frac{1}{2\xi^2} (\partial_\mu A_\mu)^2 + (\partial_\mu \bar{\chi}) D_\mu \chi$$

イロト イポト イヨト イヨト

Main difficulties (compared to QED calculations)

High-energy physics experiments

(perturbative regime of QCD)

- Strong coupling much larger $(\alpha_s \sim 0.1 \text{ vs. } \alpha \sim 1/137)$
- α_s constant grows for decreasing energy-momentum transfer
- Loop expansions much more involved (self-interactions of gluons)
- Hadrons are bound states (no free quark nor gluons ever observed)
 - Mesons: $q\bar{q}$ ($\pi^{\pm 0}$, ...)Standard HadronsExotic HadronsBaryon: qqq (P, N, ...)q qq qq qMesonBaryonq qq q
- quarks and gluons interact strongly, and electro-weak with the other elementary particles

イロト イポト イヨト イヨト

Faces of Strong Interaction physics

Experimental Side

- Hadron properties
- Scattering experiments
- High-Temperature / density
- . . .

Theory

- Quantum Chromodynamic (QCD) (QFT of strong interaction)
- Effective Models (Chirale Perturbation, HQET, ...)
- . . .

Perturbative Methods

- extensive Loop-Calculations (algebraic, numerical)
- . . .

Non-perturbative Numerical Methods

- Lattice QCD calculations (Discretized QCD)
- Numerically solving coupled QCD equations (truncated QCD)
 - Bound-state equations
 - Dyson-Schwinger equations

イロト イポト イヨト イヨト

Functional RG

• . . .

Lattice regularization of QCD (LQCD)

QCD action

$$S_{\rm QCD} = \int d^4 x \, \left[-\frac{1}{2g_0^2} \operatorname{Tr} F^2[A] \, + \, \sum_f \bar{\psi}^f_x \left(\not\!\!D[A] - m_0^f \right) \psi^f_x \right]$$

Discretization of Euclidean space-time

• Introduce 4-dim lattice $L^3 \times T$

$$x = n a^4, \quad n \in \mathbf{Z}^4$$

- Quark fields $\psi, \bar{\psi}$ dwell on sites
- But: naive discretization of gluon field $A_{\mu}(x)$ not gauge-invariant at finite a

イロト イポト イヨト イヨ

Lattice regularization of QCD (LQCD) introduced by K. Wilson (1974-77)

$$U_{\mu}(n) = \mathcal{P}e^{iag_0 \int_n^{n+\hat{\mu}} A_{\mu}(z)dz} \quad \in SU_c(3)$$

Using "links" $U_{\mu}(n)$ discretized action for

Example: unimprove

$$U_{\mu}(n) = \mathcal{P}e^{iag_{0}\int_{n}^{n/\mu}A_{\mu}(z)dz} \in SU_{c}(3)$$

$$g^{"links"} U_{\mu}(n) \text{ gives a gauge-invariant}$$

$$T$$

$$U_{\mu\nu}(n) = \prod_{n+\mu}^{n+\mu+} U_{\mu\nu}(n) = \prod_{n+\mu}^{n+\mu+} U_{\mu\nu}(n) = \prod_{n+\mu}^{n+\mu+} U_{\mu\nu}(n) = \prod_{n+\mu}^{n+\mu+} U_{\mu\nu}(n) = \prod_{n+\mu+\mu+\mu}^{n+\mu+} U_{\mu\nu}(n) = \prod_{n+\mu+\mu+\mu+\mu+\mu+\mu+\mu}^{n+\mu+\mu+\mu+\mu+\mu+\mu+\mu}$$

$$M_{LQCD} = M_{LQCD} = M_{LQCD}$$

• Fermion matrix:
$$M_{nm}^{W}[U, \kappa_{f}] = \delta_{nm} - \kappa_{f} \sum_{\pm \mu} \delta_{m,n+\hat{\mu}} (1 + \gamma_{\mu}) U_{\mu}(n)$$

 $eta \equiv 6/g_0^2, \qquad \kappa_f \equiv 1/(2m_0^f-8)$ **QCD** Parameters:

Other (improved) discretizations possible, requirement: $S_{LQCD} \xrightarrow{a \to 0} S_{OCD}$

A. Sternbeck (Uni Jena)

・ロト ・四ト ・ヨト ・ヨト

 $\frac{U_{\mu}(n)}{\psi(n), \bar{\psi}(n)}$

Lattice QCD calculation

Expectation value of an observable via path integral

$$\langle \mathcal{O} \rangle = \frac{1}{Z} \int \prod_{n\mu} dU_{n\mu} \, \underline{d\bar{\psi}_n \, d\psi_n} \, \mathcal{O}[U, \bar{\psi}, \psi] \, e^{-(S_g[U] + S_f[U, \bar{\psi}, \psi])}$$

- No gauge-fixing needed! (compact gauge group)
- Integrate over quark fields exactly modified action and integrand (non-local functional of links U)
- Left: Master integral for expectation value

$$\langle \mathcal{O} \rangle_{\beta,\kappa,L} = \frac{1}{Z} \int \prod_{n\mu} dU_{n\mu} \ F_{\mathcal{O}}[U] \ e^{-S_{\text{eff}}[U,\beta,\kappa]}$$

• Effective (partly integrated) action

$$S_{eff}[U;eta,\kappa] = S_{g}[U;eta] + \log \det M[U;\kappa]$$

イロト 不得下 イヨト イヨト

Lattice QCD calculation

Monte-Carlo calculation

Master integral is very-high dimensional integral

$$\langle \mathcal{O} \rangle_{\beta,\kappa,L} = \frac{1}{Z} \int \prod_{n\mu} dU_{n\mu} F_{\mathcal{O}}[U] e^{-S_{\text{eff}}[U,\beta,\kappa]}$$

- Number of integration variables $(N_c = 3, N_d = 4)$ $64^3 \times 128 \times (N_c^2 - 1) \times N_d = 1\,073\,741\,824$ $16^3 \times 32 \times (N_c^2 - 1) \times N_d = 4\,194\,304$
- Estimate integrals stochastically

イロト 不得下 イヨト イヨト

Monte-Carlo integration: Sample links U with probability density ("important sampling")

$$P[U^{(i)}] = \frac{1}{Z} e^{-S_{eff}[U^{(i)}]} \qquad \text{Markov chain:} \quad U^{(1)}, U^{(2)}, \dots, U^{(N)} \quad \in SU(3)$$

Estimate for expectation value:
$$\overline{\mathcal{O}} \equiv \frac{1}{N} \sum_{i=1}^{N} \hat{\mathcal{O}}[U^{(i)}] \quad \xrightarrow{N \to \infty} \quad \langle \mathcal{O} \rangle_{\beta,\kappa,L}$$

Monte-Carlo / Stochastic integration: How does it work? $\ensuremath{\texttt{1-dim\ example}}$

$$f(x) = (1 - x^2) \cdot e^{-x^2}, \quad I = \int_{-1}^{1} f(x) dx = \frac{1}{e} + \frac{\sqrt{\pi}}{2} Erf(1) \simeq 1.1147035$$

• Numerical integration with rectangular rule

$$I \simeq \sum_{i=1}^{N} f(x_i) \Delta x, \qquad \Delta x = \frac{x_2 - x_1}{N}$$

イロト イヨト イヨト イヨ

Monte-Carlo / Stochastic integration: How does it work? $\ensuremath{\texttt{1-dim\ example}}$

$$f(x) = (1 - x^2) \cdot e^{-x^2}, \quad I = \int_{-1}^{1} f(x) dx = \frac{1}{e} + \frac{\sqrt{\pi}}{2} Erf(1) \simeq 1.1147035$$

• Numerical integration with rectangular rule

$$I \simeq \sum_{i=1}^{N} f(x_i) \Delta x, \qquad \Delta x = \frac{x_2 - x_1}{N}$$

• Stochastic sampling of $x_i \in [-1:1]$ with $p(x) \propto 1$

$$I \simeq (x_2 - x_1) \cdot \frac{1}{N} \sum_{i=1}^N f(x_i) = (x_2 - x_1) \cdot \langle f \rangle_N$$

Monte-Carlo / Stochastic integration: How does it work? $\ensuremath{\texttt{1-dim example}}$

$$f(x) = (1 - x^2) \cdot e^{-x^2}, \quad I = \int_{-1}^{1} f(x) dx = \frac{1}{e} + \frac{\sqrt{\pi}}{2} Erf(1) \simeq 1.1147035$$

• Numerical integration with rectangular rule

$$I \simeq \sum_{i=1}^{N} f(x_i) \Delta x, \qquad \Delta x = \frac{x_2 - x_1}{N}$$

• Stochastic sampling of $x_i \in [-1:1]$ with $p(x) \propto 1$

$$I \simeq (x_2 - x_1) \cdot \frac{1}{N} \sum_{i=1}^{N} f(x_i) = (x_2 - x_1) \cdot \langle f \rangle_N$$

• Improved Estimator: sample with $p(x) \propto (1 - x^2)$

$$I \simeq (x_2 - x_1) \cdot \frac{1}{N} \sum_{i=1}^{N} p(x_i) \frac{f(x_i)}{p(x_i)} = (x_2 - x_1) \cdot \langle f/p \rangle_p$$

Efficiency: stochastic integration wins when ${\rm dim}\,>10$

イロト イポト イヨト イヨ

Systematics

LQCD comes with the same parameters as QCD (coupling, quark masses and volume)

$$\langle \mathcal{O} \rangle_{\beta,\kappa,L} = \frac{1}{Z} \int \prod_{n\mu} dU_{x\mu} \ F_{\mathcal{O}}[U] \ e^{-S_{eff}[U,\beta,\kappa]} = \left\langle F_{\mathcal{O}}[U^{(i)}] \right\rangle_{p(\beta,\kappa)}$$

Parameters: $\beta \equiv 6/{g_0}^2$, $\kappa_f \equiv 1/(2m_0^f - 8)$ tune them to "physical point", e.g.,

$$\frac{aM_2}{aM_1}(\beta,\kappa) \xrightarrow{\beta,L \text{ large}} R_{21}(\kappa) \xrightarrow{\kappa^f \to \kappa_c^f} \frac{M_2^{\text{phys}}}{M_1^{\text{phys}}}$$

Access to lattice spacing via physical observable ightarrow $a = a(eta,\kappa) pprox a(eta)$

Challenge: Control over systematic error when extrapolating to physical point

イロン イヨン イヨン イヨン 三日

Landscape of lattice simulations

Status

- $N_f = 2, N_f = 2+1, N_f = 2+1+1$
- Lattice spacings: $a \ge 0.04 \text{ fm}$, Volumes: $L \le 6 \text{ fm}$

compiled by S. Collins (Regensburg)

A D > A B > A B >

- Much progress in last ten years (algorithmic and computationally)
- Many lattice collaborations reach physical point (hadron masses)
- Safe extrapolation to continuum limit often remains (no always an issue)

Calculations close to physical point very expensive

Monte-Carlo chain needs numerical inversion for every step: $[\mathcal{D}(U) + m_f]^{-1}$

Require

- Volume large enough: Lightest hadron is pion with $m_\pi^2 \propto (m_u + m_d)$
- Lattice fine enough:

discretization effects small

Rule of thumb: $Lm_{\pi} \geq 4$

イロト イヨト イヨト イヨト

Lattice QCD often requires supercomputers and highly efficient codes

- Estimate integrals stochastically

イロト 不得下 イヨト イヨト

Monte-Carlo integration: Sample links U with probability density ("important sampling")

$$P[U^{(i)}] = \frac{1}{Z} e^{-S_{eff}[U^{(i)}]} \qquad \text{Markov chain:} \quad U^{(1)}, U^{(2)}, \dots, U^{(N)} \quad \in SU(3)$$

Estimate for expectation value:
$$\overline{\mathcal{O}} \equiv \frac{1}{N} \sum_{i=1}^{N} \hat{\mathcal{O}}[U^{(i)}] \quad \xrightarrow{N \to \infty} \quad \langle \mathcal{O} \rangle_{\beta,\kappa,L}$$

Main numerical challenge

Solving a linear system

For each U (varies strongly) solve linear system again, again and again

$$D(U)\cdot \vec{\psi} = \vec{b} \qquad o \qquad \vec{\psi} = D^{-1}(U)\cdot \vec{b}$$

D(U): sparse matrix, $\mathbb{C}^{12V \times 12V}$ elements, mostly zero

 \vec{b} : \mathbb{C}^{12V} elements, for $V = 64^3 \times 128 \doteq 402\,653\,184$ elements

Numerical solution needed for:

- Monte-Carlo chain
- many observable (whenever quarks are part of the operator)

Problem:

- Simulation parameters β, κ directly connected to phys. parameters
- Physical limit very expensive ("Critical slowing down")
- Reason: eigen vectors for smallest eigenvalues

Standard-Trick: Präkonditionierung

Solver

- typical: Krylov-space methods
- Number of iterations grows $\propto 1/\lambda_0$

Präconditioning

$$A \cdot \psi = b$$
$$LA \cdot R\psi = Lb$$

- if $LAR \simeq \mathbb{I}$, then $LA \cdot \tilde{\psi} = \tilde{b}$ found fast and so $\psi = R^{-1} \bar{\psi}$
- additional numerical costs vs. reduction of number of iterations

Typical methods used for lattice QCD

- Domain decomp. (checkerboard, DD, Hasenbusch trick)
- Multigrid (MG)
- Helps but can <u>not</u> to avoid "critical slowing down"

Deflation

 Determination of Eigen space for smallest EV λ₀, λ₁,...

$$A\psi^{(n)}=\lambda_n b$$

- Find solution in remaining space (orthogonal to eigen space)
- helps a lot but similar expensive as original system

イロト イポト イヨト イヨト

Empirical fact

Lowest EV for fermion matrix

- if reduced to small space region $(4^4, 6^4)$, build lower dimensional eigen space
- EV are local coherent, reason unknown, but seen empirically (maybe connected toχ-Symmetry breaking in QCD)
- i.e. approximation of eigen space sufficient (inexact deflation)
- Combined with Domain-Decomposition (DD) or MG

イロト 不得下 イヨト イヨト

- Used in recent years in several algorithms, in particular AMG
- allows lattice QCD calculations at physical point (expensive but possible)

Examples for typical lattice QCD calculations

(ロ) (回) (三) (三)

Extracting physics from LQCD calculations

Typical observables

- Plaquette or other Wilson loops
- Chiral condensates
- Hadronic properties (e.g., masses, decay constants, form factors, structure functions...)
- Fundamental parameters of QCD (strong coupling, quark masses)

• . . .

Will illustrate calculation of

- Wilson loop: quark confinement
- 2-point functions: Hadron masses
- **3**-point functions: Hadron structure

イロト 不得下 イヨト イヨト

Extracting Wilson loops

Wilson loops

- Allow to estimate potential between (two) static color sources.
- Prototype of gauge-invariant observable (purely gluonic)
- Also used as operators for gluonic bound states (glueballs) (from exponential decay of correlation function)

Wilson Loop on gauge field configuration U

Expectation value

$$\langle W \rangle_{R,T} = \frac{1}{Z} \int DU W[U] e^{-S_{eff}[U]} = \frac{1}{N} \sum_{i=1}^{N} W[U^{(i)}] + O\left(\frac{1}{\sqrt{N}}\right)$$
$$\propto e^{-tV(r)} \left(1 + O(e^{-t\Delta E})\right)$$

Static quark potential from expectation values of Wilson loops

Static quark potential

$$V(r) = A + \frac{B}{r} + \sigma r$$

- Force between quarks is dV/dr
- A irrelevant
- 2nd term: Coulomb term with strength *B*
- 3^{rd} term: lin. rising potential σ is string tension (\approx 900 MeV/fm)

Linear rising potential:

energy rises the further quark and antiquark are pulled apart (quark confinement) Lattice Data for quen. approximation (no sea quarks)

String formation and breaking

Full QCD: If QCD vacuum contains "sea quarks" (unquenched)

- creation of sea quark-antiquark pairs at sufficient energy
- flux tube breaks for large enough r

SESAM-Collaboration: Bali et al. (2005)

Extracting physics from LQCD calculations

Typical observables

- Plaquette or other Wilson loops
- Chiral condensates
- Hadronic properties

(e.g., masses, decay constants, form factors, structure functions...)

• . . .

Will illustrate calculation of

- Wilson loop: quark confinement
- 2-point functions: Hadron masses, decay constants
- **3**-point functions: hadron structure, renormalization etc.

イロト 不得下 イヨト イヨト

Hadronic two- and three-point functions on the lattice

2-point correlation functions

$$C_{2pt}^{h}(\vec{p},t) = \frac{1}{\sqrt{V_{S}}} \sum_{\vec{x}} e^{i\vec{x}\cdot\vec{p}} \left\langle \bar{h}(\vec{x},t) h(\vec{0},0) \right\rangle_{U} \stackrel{(\vec{p}=0)}{=} |Z_{0}|^{2} e^{-m_{0}t} + |Z_{1}|^{2} e^{-m_{1}t} + \dots$$

3-point correlation functions

$$C_{3\rho t}^{\mathcal{O}}(\tau, t, \vec{p}, \vec{p}') = \frac{1}{\sqrt{V_S}} \sum_{\vec{x}} e^{i \vec{x} \cdot \vec{p}} e^{i \vec{z} \cdot \vec{\Delta} P} \left\langle h(t, \vec{x}) | \mathcal{O}(\tau, z) | \bar{h}(0, \vec{0}) \right\rangle_{U}$$
$$= prefactor(t, \tau, \vec{p}, \vec{p}') \otimes \langle H | \mathcal{O} | H \rangle + \dots$$

- Interpolation operators h have quantum number of hadron
 - Proton: $h_{p^+}(x) = \varepsilon^{abc} \{ u^{aT}(x) C \gamma_5 d^b(x) \} u^c(x)$ Proton: $h_{m^+}(x) = \overline{d}(x) \gamma_5 u(x),$

 $x = (\vec{x}, t)$

- Insertion operator \mathcal{O} chosen wrt. desired matrix element
 - Vector current: $\bar{\psi}\gamma_{\mu}\psi$
 - Axial-Vector current: $\bar{\psi}\gamma_{\mu}\gamma_{5}\psi$

Extracting physics from LQCD calculations

Typical observables

- Plaquette or other Wilson loops
- Chiral condensates
- Hadronic properties (e.g., masses, decay constants, form factors, structure functions...)
- Fundamental parameters of QCD (strong coupling, quark masses)

• . . .

Will illustrate calculation of

- Wilson loop: quark confinement
- 2-point functions: Hadron masses
- 3-point functions: Hadron structure

イロト 不得下 イヨト イヨト

Hadron structure functions

Form factors: Spatial distribution of charge and magnetization

Partondistribution: Distribution of momentum and spin

Generalized parton distribution (GPDs): correlated distribution of momentum, spin, charge

イロト イヨト イヨト イヨト

Goal: Determination of non-pertubative functions directly from QCD

- Form factors possible from lattice QCD
- GPDs, PDFs: only moments accessible so far (Ji'13: quasi-PDFs possible)

Pion form factor Experiment vs. Lattice

イロン イロン イヨン イヨン

Moments of Parton Distributions (PDFs)

Nucleon parton distribution function

- Important for phenomenology
- Known for large range of x = [0, 1] (long. mom. fraction)
- Good knowledge for *u* and *d*
- For other quarks not as good

Lattice QCD

Moments of nucleon PDF

$$\langle x^n \rangle_{(q)} = \int_0^1 dx \, x^n \left[q(x) + \bar{q}(x) \right]$$

• New: indirect access to q(x) itself

Spin structure of the Nucleon

Naive Parton model

• Nucleon spin = sum of valence quark spins

• "Spin puzzle/crisis": E μ -Collaboration (1989) found: $\Delta\Sigma \approx 0.120$

Modern view

- Valence quarks contribute only a fraction
- Significant contribution also from gluons and sea quarks
- Also important: Orbital angular momentum L of quarks and gluons

• Total spin:

$$\frac{1}{2} = \frac{1}{2} \underbrace{\left(\Delta u + \Delta \bar{u} + \Delta d + \Delta \bar{d} + \Delta s + \Delta \bar{s}\right)}_{\Delta \Sigma} + L_q + \Delta g + L_g$$

• Individual contributions can be calculated using lattice QCD ^{Bali et al., PRL108 (2012) 222001} $\Delta s + \Delta \bar{s} = -0.020(10)(4)$ $\Delta \Sigma = \Delta u + \Delta \bar{u} + \Delta d + \Delta \bar{d} + \Delta s + \Delta \bar{s} = 0.45(4)(9)$

イロト 不得下 イヨト イヨト

now

Spin structure of the Nucleon

Naive Parton model

• Nucleon spin = sum of valence quark spins $\Delta \Sigma = 1$

$$\Delta d_v = -rac{1}{3}$$
 1980s now

イロト 不得下 イヨト イヨト

$$\frac{1}{2} = \frac{1}{2} \left(\Delta u_v + \Delta d_v \right) \quad \text{where} \quad \Delta u_v = \frac{4}{3}, \Delta d_v = -\frac{1}{3} \quad \text{1980s}$$

• "Spin puzzle/crisis": E μ -Collaboration (1989) found: $\Delta\Sigma \approx 0.120$

Modern view

- Valence quarks contribute only a fraction
- Significant contribution also from gluons and sea quarks
- Also important: Orbital angular momentum L of quarks and gluons

• Total spin:

$$\frac{1}{2} = \frac{1}{2} \underbrace{\left(\Delta u + \Delta \bar{u} + \Delta d + \Delta \bar{d} + \Delta s + \Delta \bar{s}\right)}_{\Delta \Sigma} + L_q + \Delta g + L_g$$

• Moments of GPDs deliver total quark momentum

$$\frac{1}{2} = \frac{1}{2}\Delta\Sigma + L_q + \Delta g + L_g$$

Extracting physics from LQCD calculations

Strong coupling from QCD phenomenology and lattice QCD

Wrapping up

Lattice QCD

- Provides numerical access to many quantities of strong interaction physics
- Systematically improvable, becomes QCD in the respective limits
- Needs usage of supercomputers and parallel programming
- Success nicely demonstrates correctness of QCD

— Thank you for your attention! —

イロト 不得下 イヨト イヨト
